

Since your [Show Time](#) project is now running as a permanent background service, you don't need to stay logged into the terminal. However, you should keep these "survival" commands handy for whenever you want to update your site or check its health.

❑ Management Commands

These are the most important commands for controlling your website's "engine."

Command	What it does
<code>sudo systemctl status showtime</code>	Check Health: Shows if the site is "Active (running)" or if it has crashed.
<code>sudo systemctl restart showtime</code>	Refresh Site: Run this after you edit your code to make the changes appear live.
<code>sudo systemctl stop showtime</code>	Turn Off: Takes the website offline immediately.
<code>sudo systemctl start showtime</code>	Turn On: Brings the website back online if it was stopped.
Export to Sheets	

❑ Editing & Viewing Commands

Use these to manage your files and see what's happening inside the code.

Command	What it does
<code>cd ~/ShowTimeAwsProject</code>	Go Home: Moves you into your project folder where your code lives.
<code>ls -l</code>	List Files: Shows all your project files and who has permission to edit them.
<code>sudo nano app.py</code>	Edit Code: Opens your main Python file so you can change features or fix bugs.
<code>sudo journalctl -u showtime -f</code>	Live Logs: Shows you real-time errors or visitor traffic (very helpful for debugging).

□ System & Port Commands

For port 80 we use

sudo nano /etc/systemd/system/showtime.service (in aws console)

then

copy and put code through paste through (ctrl+insert) keys

code is : (

[Unit]

Description=Gunicorn instance to serve ShowTimeAwsProject

After=network.target

[Service]

User=ec2-user

Group=ec2-user

WorkingDirectory=/home/ec2-user/ShowTimeAwsProject

AmbientCapabilities=CAP_NET_BIND_SERVICE

Environment="FLASK_SECRET_KEY=dev_key_\$(date +%s)"

ExecStart=/usr/local/bin/gunicorn --workers 3 --bind 0.0.0.0:80 app:app

Restart=always

[Install]

WantedBy=multi-user.target

)

For port 5000 we use

sudo nano /etc/systemd/system/showtime.service (in aws console)

then

copy and put code through paste through (ctrl+insert) keys

code is : (

[Unit]

Description=Gunicorn instance to serve ShowTime

After=network.target

[Service]

User=ec2-user

Group=ec2-user

WorkingDirectory=/home/ec2-user/ShowTimeAwsProject

AmbientCapabilities=CAP_NET_BIND_SERVICE

Environment="FLASK_SECRET_KEY=dev_key_\$(date +%s)"

ExecStart=/usr/local/bin/gunicorn --workers 3 --bind 0.0.0.0:5000 app:app

Restart=always

[Install]

WantedBy=multi-user.target

)

Use these if you need to change how the server talks to the internet.

Command	What it does
<code>sudo nano /etc/systemd/system/showtime.service</code>	Configuration: Use this to change your Port (like moving from 5000 to 80). This use for create or edit if exist.
<code>sudo systemctl daemon-reload</code>	Update System: Must be run every time you edit the <code>.service</code> file.
<code>top</code>	Task Manager: Shows how much CPU and RAM your EC2 instance is using.

❑ Pro-Tip for your Project

I noticed on your [AWS EC2 Dashboard](#) that you have two instances: **FinallShowTime** (Running) and **ShowTime** (Stopping).

Since you are on the **AWS Free Tier**, make sure you eventually terminate (delete) any instances you aren't using so you don't run out of free hours!

Would you like to know how to set up a "Live Log" view so you can see whenever someone clicks a movie on your site?

From starting to make instance and launce it

Setting up a second instance is a great way to test your new "Forgot Password" and SMS features without breaking your live site. Since you already have the [Show Time](#) site running, this will feel very familiar.

Here are the commands you need to run on your **new** instance to get everything working from scratch:

1. System Preparation

First, update the server and install the "tools" needed to talk to GitHub and run Python.

Bash

```
sudo yum update -y
sudo yum install git python3-pip -y
```

2. Clone Your Project

Bring your code from [GitHub](#) onto this new server:

Bash

```
git clone https://github.com/mayankchauhan61z1/ShowTImeAwsProject.git
cd ~/ShowTImeAwsProject
```

3. Install Requirements

```
pip3 install -r requirements.txt
```

Install Flask, Boto3 (for SNS/DynamoDB), and Gunicorn:

Bash

```
pip3 install flask boto3 gunicorn
```

4. Create the Service (The "Permanent" Part)

This is the step that makes it run forever. Open a new service file:

Bash

```
sudo nano /etc/systemd/system/showtime.service
```

Paste this configuration (same as before) for port 80:

```
[Unit]
Description=Gunicorn instance to serve ShowTImeAwsProject
After=network.target

[Service]
User=ec2-user
Group=ec2-user
WorkingDirectory=/home/ec2-user/ShowTImeAwsProject
```

```
AmbientCapabilities=CAP_NET_BIND_SERVICE
Environment="FLASK_SECRET_KEY=dev_key_$(date +%s) "
ExecStart=/usr/local/bin/gunicorn --workers 3 --bind 0.0.0.0:80 app:app
Restart=always
```

```
[Install]
```

```
WantedBy=multi-user.target
```

5. Start the Engine

Run these three commands to activate the website:

Bash

```
sudo systemctl daemon-reload
sudo systemctl enable --now showtime
```

❑ Critical Step: AWS Console Setup

Even with the right commands, the site won't work unless you do these two things in the [AWS Console](#):

1. **Security Group:** Ensure the new instance has **Port 80 (HTTP)** open to 0.0.0.0/0.
2. **IAM Role:** Attach your `Movie_Platform` role to the new instance so your "Forgot Password" SNS code has permission to send SMS.

Summary of Workflow for your New Code:

1. **Code on GitHub:** Update your code with the AI's "Forgot Password" logic.
2. **Pull to EC2:** Run `git pull` on the new instance.
3. **Restart:** Run `sudo systemctl restart showtime`.
